ABSTRACT

An HPLC method for simultaneous determination of arenaric acid (1), verbascoside (2), 6-hydroxyluteolin (3), 6-hydroxyluteolin-7-O-glycoside (4), and nodifloretin (5) from *Lippia nodiflora* in rat plasma was developed and validated. The optimal chromatographic separation was achieved with a gradient mobile phase comprising 0.1 % aqueous acetic acid and acetonitrile. The limit of detection was 78.1 ng/mL for 3 and 39.1 ng/mL for the other compounds (signal-to-noise ratio = 3), whereas the limit of quantification was 312.5 ng/mL for 3 and 156.3 ng/mL for the other compounds (signal-to-noise ratio = 12). The recovery values of compounds 1–5 ranged from 89.37–100.92 %. Their accuracy values were between 96.48 and 105.81 %, while their corresponding precision values were in the range of 0.75–9.06 % for both intraday and inter-day analysis. The method was then applied in the first pharmacokinetic study of 1–5. Following intravenous administration, 1–5 were eliminated slowly from the body with a mean clearance value of 0.11, 0.13, 0.30, 0.09, and 0.23 L/kg h, respectively. Meanwhile, their peak plasma concentration upon oral administration was 8.97, 1.07, 1.06, 0.65, and 0.38 µg/mL, respectively. Compound 3 (5.97 %) exhibited the highest absolute oral bioavailability value, followed by 1 (5.22 %), 4 (3.13 %), 2 (2.10 %), and 5 (0.93 %).

ABBREVIATIONS

AUC	area under the curve (AUC)
CV	coefficient of variation
LOD	limit of detection
LOQ	limit of quantification

r^2	coefficient of determination
SEM	standard error of the mean

Introduction

Lippia nodiflora (L.) Michx., also known as *Phyla nodiflora* (L.) Greene [1, 2], is a fast-growing creeping perennial medicinal herb belonging to the Verbenaceae family [3]. It is commonly known as Frog Fruit and has been traditionally used for the treatment of knee joint pain, lithiasis, diuresis, urinary disorders, and swelling [1–5]. The plant is rich in flavonoids [6–9], phenols [10], triterpenoids, and steroids [11, 12]. Pharmacological studies have shown that the plant possesses a broad array of biological properties, including anti-urolithiasis [13], antihypertensive [14], antioxidant [15], antitumor [16], and anti-inflammatory [17] activity. In addition, our previous study indicated that phenylethanoid glycosides and flavonoids of *L. nodiflora* were promising xanthine oxidase inhibitors [18]. Two phenylethanoid glycosides, namely, arenarioside (**1**) and verbascoside (**2**), together with three flavonoids, namely, 6-hydroxyluteolin (**3**), 6-hydroxyluteolin-7-O-glycoside (**4**), and nodifloretin (**5**), isolated from *L. nodiflora* were shown to have an antihyperuricemic effect in potassium oxonate- and hypoxanthine-induced hyperuricemic rats, with **3** being the most active [19].

Due to the promising uric acid-lowering benefit of the phenylethanoid glycosides and flavonoids reported previously [18, 19], the characterization of their bioavailability and pharmacokinetic properties is important for their further development into phytopharmaceuticals. Hitherto, there is no report on the pharmacokinetic data of those antihyperuricemic constituents, except verbascoside. In addition, no analytical method has been developed for the simultaneous determination of the bioavailability and pharmacokinetics of bioactive compounds **1–5** in rats. The only study found was on the pharmacokinetic of acteoside, also known as verbascoside, from *Plantago asiatica* or *Cistanche deserticola* using liquid chromatography-mass spectrometry [20], liquid chromatography-tandem mass spectrometry [21, 22], or liquid chromatography with amperometric detection [23]. Previously, we developed, validated, and applied an HPLC method for the phytochemical analysis of the antihyperuricemic constituents **1–5** in the plant samples [24]. In the present study, we aimed at the development of a simple and reliable HPLC method with a UV detection method for the simultaneous determination and quantification of the antihyperuricemic constituents **1–5** in rat plasma and to apply the method in the pharmacokinetic study of those bioactive compounds in rats after oral and intravenous administration.

Results and Discussion

In the present study, a simple and reliable HPLC method was developed and validated. It uses UV detection and gradient elution with a mobile phase consisting of 0.1 % aqueous acetic acid (solvent A) and acetonitrile (solvent B) for the simultaneous determination and quantification of the five antihyperuricemic constituents in rat plasma with a total run time of approximately 38 min (► Fig. 1b). Solvent A was chosen as it minimized the peak tailing effect related to the dissociation of the hydroxyl group of flavonoids compared to the acid-free solvent. Acid-containing mobile phases are often used for flavonoid separation [25–29]. Since phenylethanoid glycosides and flavonoids exhibited two different sets of UV maxima at 218 and 332 nm, and 282 and 346 nm, respectively, a wavelength of 340 nm producing a high absorbance for both phenylethanoid glycosides and flavonoids was selected for the HPLC-UV analysis.

The calibration curves for the bioactive compounds in rat plasma were linear over the concentration range investigated with a mean slope (\pm standard error of mean) of 152.00 ± 3.75 , 233.38 ± 1.25 , 540.33 ± 3.53 , 627.10 ± 5.05 , and 267.93 ± 5.31 for **1**, **2**, **3**, **4**, and **5**, respectively. In addition, the coefficient of determination for the calibration curve of all five compounds was equal to or greater than 0.9996 (► Table 1). The LOD value was 78.1 ng/mL for **3** and 39.1 ng/mL for the rest of the compounds at a signal-to-noise ratio of 3. On the other hand, the LOQ value for **3** was 312.5 ng/mL, whilst for the rest of the compounds, it was 156.3 ng/mL at a signal-to-noise ratio of 12. The recovery of bioactive compounds **1–5** ranged from 89.37–100.92 % (► Table 2), implying that deproteinization of the plasma with methanol did not result in any substantial loss of the chemical constituents. The accuracy values were between 97.95 and 105.81 % for intraday analysis and between 96.48 and 101.13 % for inter-day analysis. Meanwhile, the corresponding precision values were ranged from 1.15–9.06 % for intraday analysis and ranged from 0.75–7.71 % for inter-day analysis. Both accuracy and precision values indicated that the developed method was reliable and reproducible for the simultaneous determination of the five bioactive chemical constituents in rat plasma.

The developed and validated HPLC method was then successfully applied to simultaneously determine and quantify the 5 antihyperuricemic constituents in the plasma of rats. Rats were administered, either orally (20 mg/kg each of **1–5**) or intravenously (2 mg/kg each of **1–5**), a mixture of **1–5**, consisting of **1**, **2**, **3**, **4**, and **5** in a ratio of 1:1:1:1:1. The bioactive phenylethanoid glycosides and flavonoids were unambiguously identified as **1–5** in the rat plasma upon comparison of the retention times with those of their respective standards, as shown in the ► Fig. 1. The chromatogram of blank rat plasma is shown in ► Fig. 1a–c shows the chromatogram of rat plasma spiked with bioactive compounds **1–5** at a concentration of 5 μ g/mL each, whereas ► Fig. 1d shows the chromatogram of rat plasma 1 h after intravenous administration of the mixture of **1–5** (2 mg/kg each of **1–5**).

(► Fig. 2a, b) illustrates the mean plasma concentration-time profiles of phenylethanoid glycosides and flavonoids after intravenous administration of the mixture of **1–5**. Following intravenous administration, compounds **1–5** showed a gradual decline in the plasma concentration starting from the highest concentration at 0 h. Interestingly, the concentrations of phenylethanoid glycosides

► **Fig. 1** HPLC chromatogram from the analysis of arenarioside (**1**), verbascoside (**2**), 6-hydroxyluteolin (**3**), 6-hydroxyluteolin-7-O-glycoside (**4**), and nodifloretin (**5**). **a** Blank rat plasma. **b** Mixed standards (10 µg/mL each of **1–5**) isolated from *L. nodiflora*. **c** Rat plasma spiked with **1–5** (5 µg/mL each). **d** Rat plasma 1 h after intravenous administration of the mixture of **1–5** (2 mg/kg each of **1–5**).

► **Table 1** Regression equations, correlation coefficients, linear ranges, and limits of detection and quantification of the antihyperuricemic constituents (**1–5**) of *L. nodiflora*.

Compound	Regression equation	r^2	Linear range (ng/mL)	LOD (ng/mL)	LOQ (ng/mL)
Arenarioside	$y = 152.00x - 20.39$	0.9999	156.3–20000	39.1	156.3
Verbascoside	$y = 233.38x - 58.81$	0.9997	156.3–20000	39.1	156.3
6-Hydroxyluteolin	$y = 540.33x - 371.64$	0.9996	312.5–20000	78.1	312.5
6-Hydroxyluteolin-7-O-glycoside	$y = 627.10x - 130.44$	0.9996	156.3–20000	39.1	156.3
Nodifloretin	$y = 267.93x + 59.24$	0.9996	156.3–20000	39.1	156.3

found in the rat plasma after intravenous administration was higher than those of the flavonoids, with **1** exhibiting the highest PPC value of 11.07 ± 0.93 µg/mL, while **2** showed the second highest PPC value of 8.75 ± 1.10 µg/mL, followed by **4**, **5**, and **3** with their corresponding PPC values of 8.12 ± 0.45 , 5.89 ± 0.67 , and 4.13 ± 0.57 µg/mL, respectively.

► **Fig. 3a, b** illustrates the mean plasma concentration-time profiles of phenylethanoid glycosides and flavonoids after oral administration of the mixture of **1–5**. Following oral administration, all five compounds showed a rapid rise, and reached the maximal concentration in the rat plasma with a T_{max} ranging from 0.5–0.67 h, indicating that they were rapidly absorbed and entered the blood circulation system. This finding was consistent with an earlier study where a phenylethanoid glycoside, acteoside, was shown

to reach its maximal concentration in the rat plasma (0.1 µg/mL) within the first 30 min after oral administration [21]. It is important to note that **1** showed a distinctively higher concentration in the rat plasma than the rest of the compounds after oral administration, with a PPC value of 8.46 ± 0.62 µg/mL, whereas compound **5** showed the lowest concentration in the rat plasma after oral administration with a PPC value of 0.38 ± 0.01 µg/mL. The oral administration profile pattern displayed by **2** was very similar to that displayed by **3**, as indicated by their close mean maximum plasma concentration values.

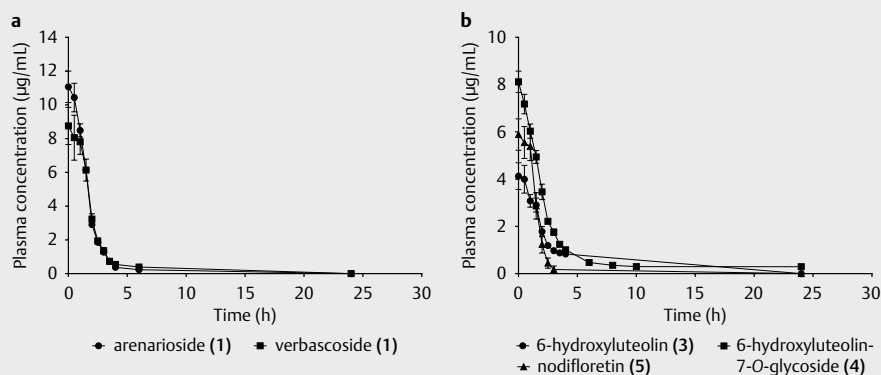

► **Table 3** summarizes the pharmacokinetic parameters of the bioactive compounds **1–5** in rat plasma after intravenous or oral administration of the mixture of **1–5**, comprising 2 mg/kg each of **1–5** or 20 mg/kg each of **1–5**, respectively. Following intravenous

administration, **3** exhibited the highest V_d value, implying that a greater amount of **3** was distributed into the tissue compartment compared to the other compounds. Remarkably, **4** exhibited the lowest mean clearance value, indicating that it has been cleared from the body slower than the other compounds. With regards to this, **4** had the longest corresponding half-life and the largest AUC value, suggesting that the tissue distributed compound **4** was retained in tissue compartment and eliminated slowly, despite its relatively small volume of distribution value. Thus, while **1**, **2**, **3**, and **5** showed a gradual decline to 0 at 24 h, **4** did not decline to 0 and still could be detected even at 24 h after both oral and intravenous administration.

Following oral administration, **1** showed the highest mean C_{max} and AUC values, despite having the largest molecular size compared to the other compounds. In contrast, **5** exhibited the lowest mean C_{max} and AUC values, suggesting that its absorption after oral administration was incomplete. In general, the plasma levels of all 5 compounds given orally were much lower than those of the intravenous administration, even though their oral doses were 10 times higher than their intravenous doses, indicating that their oral bioavailability was low and incomplete. The low oral bioavailability might be due to the first-pass metabolism reducing the concentration of the compound before it reaches the systemic circulation [30]. Nevertheless, it is interesting to note that the most potent

antihyperuricemic constituent **3** has the highest estimated absolute oral bioavailability value of 5.97 %, followed by **1**, **4**, **2**, and **5**, with estimated absolute oral bioavailability values of 5.22, 3.13, 2.10, and 0.93 %, respectively.

In conclusion, the pharmacokinetic study unveiled that the oral bioavailability of the bioactive compounds of *L. nodiflora* was low and need to be improved, thus, further study for the development of phenylethanoid glycoside and flavonoid formulations to enhance their oral bioavailability is warranted.

Materials and Methods

Chemicals and reagents

Deionized water was prepared using a Maxima ultra-pure water purifier system purchased from Elga. HPLC grade methanol and acetonitrile were purchased from Merck. Sephadex LH-20 (No. 17-0090-02) was purchased from GE Healthcare. Sodium heparin was purchased from Acros Organic. Acetic acid was purchased from System ChemAR.

Isolation of bioactive compounds

Frog Fruit [*L. nodiflora* (L.) Michx.] plants were collected from Seremban, Negeri Sembilan, Malaysia. The plant was authenticated by Dr. Rahmad Zakaria, a botanist of the Herbarium Unit, School of Biological Sciences, University of Science Malaysia (Universiti Sains Malaysia). A voucher specimen (No. 11594) was deposited at the same unit. The 5 antihyperuricemic constituents, namely, arenarioside (**1**), verbascoside (**2**), 6-hydroxyluteolin (**3**), 6-hydroxyluteolin-7-O-glycoside (**4**), and nodifloretin (**5**) (► Fig. 4), were isolated from the bioactive fraction of *L. nodiflora* following the protocol described previously [19] and were used as marker compounds for the method validation and quantification of rat plasma samples. The purity of the compounds was determined using an Agilent 1120 Compact LC system equipped with a variable wavelength photometric detector and Agilent EZ-Chrom Elite Compact Software (Agilent Technologies) [24]. The purities were found to be 97.71, 98.19, 96.25, 97.30, and 97.36 % for **1**, **2**, **3**, **4**, and **5**, respectively.

Instrumentation

The HPLC system consisted of an Agilent 1120 Compact LC system equipped with a variable wavelength photometric detector set at a wavelength of 340 nm, and Agilent EZ-Chrom Elite Compact Software (Agilent Technologies). An Inertsil ODS-3 (4.6 mm i.d. × 250 mm, GL Sciences Inc.) column pre-connected with an Inertsil ODS-3 guard column (4.6 mm i.d. × 50 mm, GL Sciences Inc.) was used for the chromatographic separation. The mobile phase consisting of 0.1 % aqueous acetic acid (A) and acetonitrile (B) was delivered with gradient elution at a flow rate of 1.0 mL/min at room temperature. The gradient elution was programmed as follows: 0–25 min, 15 % B; 25–30 min, 20 % B; 30–35 min, 36 % B; 35–38 min, 15 % B. This was followed by a 12-min equilibration period prior to the injection of each sample [24].

Sample preparation

Frozen plasma samples were thawed at the room temperature. A plasma sample (100 µL) was transferred into a 1.5-mL microcentrifuge tube and proteins were precipitated by adding 100 µL of methanol. The mixture was vortexed for 1 min using an Autovortex SA6 (Stuart Scientific) and then centrifuged at 7711 × g using a Micro 12 centrifuge (Hanil Science Industrial) for 15 min. The supernatant was transferred into a new microcentrifuge tube and 20 µL were used for injection.

Limit of detection, limit of quantification, and linearity

The calibration curves were constructed by plotting peak areas against the concentrations of the analyte prepared at 312.5, 625, 2 500, 5 000, 10 000, and 20 000 ng/mL for **3** and 156.3, 625, 2 500, 5 000, 10 000, and 20 000 ng/mL for **1**, **2**, **4** and **5**. The linearity of the curves was evaluated by linear regression analysis and was expressed as the r^2 . LOD and LOQ were determined by triplicate analysis of a series of successive twofold dilutions of the stock solutions. The LOD was defined as the lowest concentration that the analytical system can reliably differentiate from the background level and was calculated based on a signal-to-noise ratio of 3:1. The LOQ was defined as the lowest quantifiable concentration on the calibration curve and was calculated based on a signal-to-noise ratio of 12:1 [24, 31, 32].

Method validation

The method was validated through intraday and inter-day analysis of precision and accuracy according to the International Conference on Harmonisation guidelines [33]. The intraday accuracy and precision were determined for each compound by evaluating six replicate measurements of each concentration on a single day, while the inter-day accuracy and precision were determined by assessing measurements of each concentration over 6 consecutive days [24]. The recovery of the direct extraction method using methanol was calculated by comparing the peak area of the compounds after extraction with those of the compounds dissolved in the methanol at a similar concentration [24]. Accuracy was expressed as a percentage of true value, while precision was expressed as a CV [24].

► Fig. 4 The chemical structures of antihyperuricemic phenylethanoid glycosides (**1** and **2**) and flavonoids (**3–5**) isolated from *L. nodiflora*.

Animals

Male Sprague-Dawley rats (260–300 g) were obtained from the Animal Research and Service Centre of the University of Science Malaysia (Universiti Sains Malaysia) and were kept in the animal transit room of the School of Pharmaceutical Sciences, University of Science Malaysia (Universiti Sains Malaysia), Penang, Malaysia. They were maintained on a 12-h light/dark cycle at a room temperature of 25°C and were allowed free access to standard food pellets and tap water. The animals were acclimatized for 1 week prior to experimentation. The study protocol was approved by the Animal Ethics Committee, University of Science Malaysia (Universiti Sains Malaysia), Penang, Malaysia [USM/Animal Ethics Approval/2013/(89)(478)] and was in accordance with institutional guidelines (Guideline for the Care and Use of Animals for Scientific Purposes, USM) and international policies (Public Health Service Policy on Humane Care and Use of Laboratory Animal, and Guide for the Care and Use of Laboratory Animals) [34, 35].

Pharmacokinetic study

The animals were divided into two groups of three each and the study was conducted according to a two-way crossover study design. Food, but not water, was withheld overnight prior to the experimentation. Group 1 (n = 3) was intravenously injected with a mixture comprising bioactive compounds **1–5** (2 mg/kg of each compound), while group 2 (n = 3) was orally administered with a mixture consisting of bioactive compounds **1–5** (20 mg/kg of each compound). After a washout period of 2 weeks, the animals from group 1 were orally administered with a mixture of **1–5** comprising 20 mg/kg each of **1–5**, while those from group 2 were intravenously injected with another mixture of **1–5** consisting of 2 mg/kg each of **1–5**. For both routes of drug administration, the mixture of **1–5** was prepared in 20% of Tween 20 aqueous solution. The volume for intravenous injection and oral administration was 1 mL/kg and 5 mL/kg of body weight, respectively. The animals were placed in animal restraining cage during blood collection and the blood samples of 0.5 mL were collected by the tail nipping method into a sodium heparin-coated microcentrifuge tube at 0, 0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4, 6, 8, 10, and 24 h after drug administration. The blood samples were centrifuged at 4 000 × g for 15 min and the resulting plasma samples were kept frozen at –20°C prior to analysis [31].

Data analysis

The following pharmacokinetic parameters were calculated: The elimination rate constant (K_e) was calculated from the slope of plasma concentration versus time curve. The slope of the curve was equal to $K_e/2.303$. The elimination half-life ($t_{1/2}$) was determined as $0.693/K_e$, while the volume of distribution (V_d) was estimated using the equation $V_d = \text{dose}/K_e \times \text{AUC}_{0-\infty}$. The theoretical concentration at time zero (C_0) was calculated as the intercept of the semilogarithmic concentration-time curve. The area under the plasma concentration-time curve to infinity ($\text{AUC}_{0-\infty}$) was determined by combining the area from time zero to the last sampling time (AUC_{0-t}) with the area from the last sampling time to infinity ($\text{AUC}_{t-\infty}$), whereby the trapezoidal rule was applied. Total body clearance (CL) was estimated from the relationship $\text{CL} = \text{dose}/\text{AUC}_{0-\infty}$. Peak concentration (C_{max}) and time to reach C_{max} (T_{max}) following oral administration were obtained directly from the plas-

ma concentration-time plots. The absolute oral bioavailability (F) was calculated as the ratio of the dose-normalized AUC (AUC/dose) after oral and intravenous administration. The results are expressed as the mean ± SEM.

Supporting Information

The ¹H- and ¹³C-NMR, MS, UV, and IR data of **1–5** are available as Supporting Information.

Acknowledgements

The authors would like to thank the University of Science Malaysia (Universiti Sains Malaysia) for providing a grant (No. 1001/PFAR-MASI/846067) under a postgraduate research grant scheme (PRGS) to support this study. C. L. C. gratefully acknowledges the financial support by the MyPhD Scholarship from the Ministry of Education of Malaysia. C. L. C. would like to thank Dr. Liew Kok Fui for his contribution to this study.

Conflict of Interest

The authors declare that there is no conflict of interest regarding the publication of this paper.
